Ans-1-a-

A feed forward neural network (FNN) is the most basic type of artificial neural network where data moves in only one direction, from input to output, without looping back. Therefore it's very useful in the current world

It consist of following layers :-

1. Input layer : Take the input features, which could be any input dataset variable.
2. Hidden layer(s) - One or more layers where neurons perform complicated computations using weights, biases and activation functions.
3. Output layer : Produces the final result (eg. classification or regression output

Each neuron in a layer is connected to every neuron in the next layer - this is called a fully connected network. Eg use cases :- Image classification, spam detection, regression tasks
